JOURNAL OF
ENVIRONMENTAL
CHEMICAL
ENGINEERING

Journal of Environmental Chemical Engineering

Aims and Scope:

The *Journal of Environmental Chemical Engineering* (JECE) publishes full length original research papers, short communications, review papers, perspectives and letters to the Editor. Papers are welcome which apply chemical engineering principles to understand important environmental processes or that develop/optimize novel remediation processes.

The *Journal of Environmental Chemical Engineering* provides a forum for the publication of original research on the development of alternative sustainable technologies focusing on water and wastewater treatment and reuse; treatment, reuse and disposal of waste; pollution prevention; sustainability and environmental safety; recent developments on green chemistry; alternative methods of remediation of environmental accidents including but not limited to oil spills in water bodies and nuclear accidents.

JECE calls for papers that cover the following fields:

Physico-chemical processes:

Adsorption/biosorption, ion exchange, membrane processes, magnetic separation, particle separation, phase separation, multiphase extraction, thermal/evaporative processes

Advanced oxidation processes:

Heterogeneous catalysis, UV/H₂O₂, Fenton oxidation, ozonation, sonolysis, electrochemical treatment, wet air oxidation

Nanomaterials for environmental and chemical applications:

Adsorbents, catalysts, and nanocomposites

Sustainable technologies:

Water reclamation and reuse, carbon capture, renewable energy and energy recovery, waste minimization, treatment, resource recovery

JECE also covers the following fields:

- Clean synthesis and process technology
- Source control
- Process scale-up and economic analysis
- Process integration and zero liquid discharge technologies
- Resource recovery
- Water-energy nexus
- Anthropogenic activities and environmental sustainability

Editors:

Professor Despo Fatta-Kassinos, University of Cyprus, Dept of Civil and Environmental Engineering, NIREAS-International Water Research Center, P.O.Box 20537, 1678 Nicosia, Cyprus, Tel: +357 22 892275, E-mail: dfatta@ucy.ac.cy

Professor Yunho Lee, Gwangju Institute of Science and Technology, School of Environmental Science and Engineering, Oryong-dong, Buk-gu 123, Gwangju, KOREA, REPUBLIC OF, Tel: 82 (0)62 715 2468, E-mail: yhlee42@gist.ac.kr

Professor Teik-Thye Lim, Nanyang Technological University, Division of Environmental & Water Resources Engineering, Room N1-01b-47, Block N1, 50 Nanyang Avenue, Singapore, 639798, Tel: 6567906933, E-mail: cttlim@ntu.edu.sg

Professor Eder Claudio Lima, Federal University of Rio Grande do Sul, Institute of Chemistry, Av. Bento Gonçalves 9500, Postal Box 15003, Porto Alegre, BRAZIL, Tel: +55 (51) 3308 7175, Mobile: +55 (51) 92963570/ 82945656, E-mail: eder.lima@ufrgs.br

[Abstract](#) | [Close research highlights](#) | [Purchase PDF - \\$35.95](#)
- Highlights**

 - Cadmium removal is studied by abundant and low cost brown alga *S. filipendula*.
 - Optimization of process variables is carried out by RSM.
 - Experimental data followed Pseudo second order kinetic and Redlich-Peterson isotherm models.
 - Reusability of biosorbent is checked and the process is thermodynamically feasible.
- Decolorization of molasses-based distillery wastewater by means of pulse electro-Fenton process** Original Research Article

[Abstract](#) | [Purchase PDF - \\$35.95](#)
- [Influence of copper loading on mesoporous alumina for catalytic NO reduction in the presence of CO](#) Original Research Article
Pages 2350-2361
Archana Patel, Pradeep Shukla, Guan Ting Pan, Siewhui Chong, Victor Rudolph, Zhonghua Zhu
[Abstract](#) | [Close research highlights](#) | [Purchase PDF - \\$35.95](#)
- Highlights**

 - The active catalyst chemical phase is correlated with the extent of copper metal loading.
 - The catalyst activity is determined by small size of copper crystallites.
 - Catalytic site regeneration is linked to ease of charge transfer via active copper ion.
 - Various forms of TOF's are described and explored to evaluate reaction behaviour.
- [Chromium removal using adsorptive membranes composed of electrospun plasma-treated functionalized polyethylene terephthalate \(PET\) with chitosan](#) Original Research Article
Pages 2366-2377

Photocatalytic hydrogen production

ABSTRACT

In this research, carbon rod as a solid waste of primary Zinc-Carbon batteries was used as a substrate for CdS and TiO₂ film. The film was deposited by chemical bath deposition with surfactant molecules as linker agent to promote the connection between the semiconductor film and the substrate. Material characterization was conducted to understand the phases content, its surface morphology, the quantum yield (QY) as measured through isopropanol degradation, and then their activity as a photocatalyst for visible light driven photocatalytic hydrogen production. XRD analysis found that the carbon rod waste is a mechanical mixture of amorphous carbon, represented by width broad peak lying between 22 and 25° and graphitic carbon, represented by a strong (002) peak at 26.3° and also a (001) peak at 42.2°. The result shows that CdS/Carbon (CdS/C) has higher photocatalytic activity than the TiO₂/Carbon (TiO₂/C) with the quantum yield value at 380 nm of a photon is 1.651×10^{-3} . Meanwhile, TiO₂/C provide the value of 1.495×10^{-4} . The QY value of CdS/C also higher than TiO₂/C at 450 nm of the light source. The H₂ production which was conducted with CdS/C performs 1.67 times higher than the production with TiO₂/C as a photocatalyst, i.e., $0.369 \mu\text{mol s}^{-1} \text{g}^{-1}$. Meanwhile, the H₂ production rate with TiO₂/C is $0.222 \mu\text{mol s}^{-1} \text{g}^{-1}$.

1. Introduction

Photocatalytic hydrogen production has received attention due to H₂ is a clean and renewable energy resource [1]. Some different mixed metal oxide semiconductors have been studied as the photocatalyst for hydrogen production [2–5], such as TiO₂ [6–9], SrTiO₃ [10], ZrO₂ [11], Ta₂O₅ [12] and WO₃ [13]. Among of them, titanium dioxide is still the most suitable in consideration of its activity, chemical inertness, low cost and non-toxicity [14,15]. Meanwhile, Cadmium sulfide is an II–VI group of semiconductor that has a wide band gap energy of 2.4 eV. The CdS has been used as an efficient material for solar cell due to its activity under visible light. CdS is a low band-gap semiconductor, that does act as photocatalysts for hydrogen production in aqueous media [16,17]. A CdS based solid solution, i.e., Cd_{0.1}Sn_xZn_{0.9-2x}S, and Cd_{0.1}Zn_{0.9}S are known to have a high photocatalytic activity for hydrogen production under visible light radiation [18]. However, the photocatalytic activity of pure CdS semiconductor material still face some problems such as the adsorption ability of CdS toward the

reactant particles, poor photostability, and serious aggregation with each other. The aggregation could reduce their surface area and increase the recombination rate of photogenerated charge carriers, thus leading to a decreased photoactivity [19].

A significant potential of carbonaceous materials according to its absorptivity character is a promising way to overcome the low absorption ability of CdS and TiO₂. It is known that the absorptivity of fullerene attributed to increasing catalytic activity of TiO₂ [20]. Graphene quantum dots as one of the carbonaceous materials known to has the ability on electron transfer reagent anchored on TiO₂ by in situ photo-assisted strategies, and it enhanced photocatalytic H₂ evolution activity in methanol aqueous solution without the noble metal co-catalyst [21]. An ultrafast transfer of photoexcited electrons from CdS to graphene sheet could significantly decrease the recombination rate of the photoexcited electrons and holes in CdS photocatalyst [19]. Graphene also is known as a good support for anchoring well-dispersed CdS, and it efficiently suppresses the aggregation and overgrowth of CdS [19]. Other carbonaceous material, such as graphite oxide also

provide a good photocatalytic activity when it was intercalated with TiO₂. The electron transfer between TiO₂ with graphite might inhibit recombination of the excited electrons-holes [22]. Composite of CdS with all carbon form nanocomposite, such as C60, NT, RGO, and solvent-exfoliated graphene, exhibit a quite similar enhancement in the photoactivity over CdS alone if the interfacial contact between carbon and semiconductors in all samples is intimate [23]. Therefore, it has been proven by many researchers that there is a synergistic effect between carbon support and titanium dioxide layer [24]. However, fullerene C60, carbon nanotubes, RGO and also graphene are carbonaceous materials that required a specific method and equipment to synthesize. The production frequently involves the use of toxic chemicals and also the high cost of large-scale production.

In another side, solid waste batteries increase year by year due to high demand on the portable electronic devices. More than 80% of batteries sold in Europe are a primary battery, in which the large majority of primary batteries are alkaline and zinc carbon batteries [25]. Every year around 160,000 tons of consumer batteries enter the European Union [26]. Meanwhile, according to the Environmental Protection Agency (EPA), each year Americans throw away more than three billion batteries, it is comparable to 180,000 tons of batteries, in which more than 86,000 tons of these are single-use alkaline batteries [27]. Many of the components of these batteries could be recycled, avoiding the release of hazardous substances to the environment. These will contribute to the improvement of environment quality. Zinc-carbon battery is a primary or disposable battery in which a carbon rod is inserted into electrolyte mixture and serve as a cathode. The carbon rod is a good electronic conductor with inert properties. An effort to reuse those carbon rod waste became another reason to use it as a substrate in this research, instead of graphene or other well synthesized carbonaceous materials.

2. Methods

2.1. Preparation of carbon disc

The carbon disc that used in this research was prepared from carbon rod extracted from the waste of zinc-carbon primary battery (ABC battery, produced by ABC industry, Indonesia). The carbon rods were cleaned by dipped into ethanol then washed with distilled water and dried at 105 °C in the oven for 1 h. The carbon rod then being sliced into a disc with a thickness of 1 mm and the diameter is 0.8 cm. The discs were cleaned by dipped into ethanol and ultrasonicated for 15 min before then being dried at room and continued with heating at 105 °C to remove humidity. The discs were then kept in a desiccator at room temperature and were weighed gravimetrically until the weight value difference was less than 0.02 mg.

2.2. Preparation of CdS/Carbon (CdS/C)

A 500 mL CdS solution was prepared from 0.1386 g of CdSO₄, 0.1013 g thiourea as precursors and (NH₄)₂SO₄ as a complexing agent. The ammonium salt was added to the solution and serves as a buffer. In this solution, the solvent is deionized water. The carbon disc was dipped into the CdS solution. Each tablet was dipped four times for 15 min for each dipping and under 70 °C condition, as it was optimized by our previous research [28]. The prepared CdS/C discs were also gravimetrically weighed as it was done for carbon disc.

2.3. Preparation of TiO₂/Carbon (TiO₂/C)

Meanwhile, TiO₂/C was also prepared by dipping the carbon disc into the synthesis solution that consists of 1.1 g TiCl₄ in a 100 mL of 1 M HCl and added with 0.583 g of CTAB. The process was conducting for four days under 60 °C. The green prepared discs were then cleaned and heated at 450 °C for 4 h. The prepared TiO₂/C were then gravimetri-

cally weighed as it was done for carbon disc.

2.4. Material characterization and photocatalytic activity test

The prepared materials then were analyzed by X-ray diffraction (Shimadzu, Japan), a high-resolution UV–vis Spectrophotometer (UV 1700 Pharmaspec, Shimadzu, Japan) for diffuse-reflection analysis, and continued to Tauc plots analysis to determine their band gap energy.

Quantum yield (QY) of the prepared materials was measured as their activity on isopropanol degradation. A photocatalyst tablet with a diameter of 0.8 cm was into 4 mL of 2.5 M isopropanol solution in a cuvette, and then the cuvette was installed in the sample holder of UV–vis spectrophotometer (single-beam UV–vis mini 1240 spectrophotometer, Kasugawa, Shimadzu, Japan). The cuvette is a quartz box, which is usually used for UV–vis spectrophotometer analysis. The width of the cuvette is 1.2 cm, length of 1.2 cm, and a tall of 4.5 cm. The volume of isopropanol solution was 40 mL, therefore due to a small volume and homogeneous phase of isopropanol, in this research, the degradation was conducted without stirring. After isopropanol solution had poured into the cuvette, then the spectrophotometer was tuned into the photometric menu, and the sample was irradiated by UV (380 nm of wavelength) and visible wavelength (450 nm and 517 nm for CdS/C). Radiation was conducted for 90 min, and the absorbance data was recorded in every 30 min. The QY value was calculated based on Eq. (1) [29].

$$QY = \frac{N_{mol}(mol. s^{-1})}{N_{photon}(molEinstein. s^{-1})} \quad (1)$$

N_{mol} is the number of isopropanol molecules transformed into a product, or the number of product formed during degradation. Meanwhile, N_{photon} is the number of photons absorbed by a photocatalyst material as measured by UV–vis diffuse reflectance spectroscopy.

To understand the contribution of the carbon disc to the degradation activity, this research also compared the catalytic performance of CdS film when the substrate is a glass (a quartz glass). Therefore, the CdS photocatalyst was compared in the same form i.e., the CdS film.

2.5. Photocatalytic hydrogen production test

The photocatalytic test was conducted in a Pyrex flask equipped with water condenser to keep the temperature of the reaction. The ambient temperature was 25.5 °C (298.65 K), the reaction temperature was 31.0 °C (304.15 K), and the ambient pressure was 1003 mbar (0.9899 atm). The prepared catalyst tablets with a mass of 0.0633 g were poured into 50 mL 0.35 M Na₂SO₃ solution and 50 mL of 0.25 M Na₂S solution, and it was stirred during the reaction. Nitrogen gas flowed into the flask for 30 min before the reaction started. Meanwhile, a 500-W mercury lamp (UV wavelength) was used as a photon source for 5 h of radiation time. The produced gas then analyzed by Thermal Conductivity Detector-Gas Chromatography (TCD-GC) to ensure the presence of hydrogen gas and then the quantity was determined by the volumetric method. The injection of produced gas was conducted at every 1 h. The rate of hydrogen production ($\mu\text{mol s}^{-1} \text{g}^{-1}$) was calculated for each catalyst to understanding the photocatalytic activity on H₂ production.

3. Result and discussion

Morphological analysis by Scanning Electron Microscope (SEM, JEOL JSM-6510, Germany) resulted in images as described in Fig. 1. The carbon disc shows a rough and non-homogeneous surface morphology (Fig. 1(a)). However, it became smooth and more homogenous after CdS deposition, as well as after TiO₂ deposition. CdS were deposited as flakes (Fig. 1(b) insert). Meanwhile, TiO₂ was deposited as small spheres with the size of less than 200 μm .

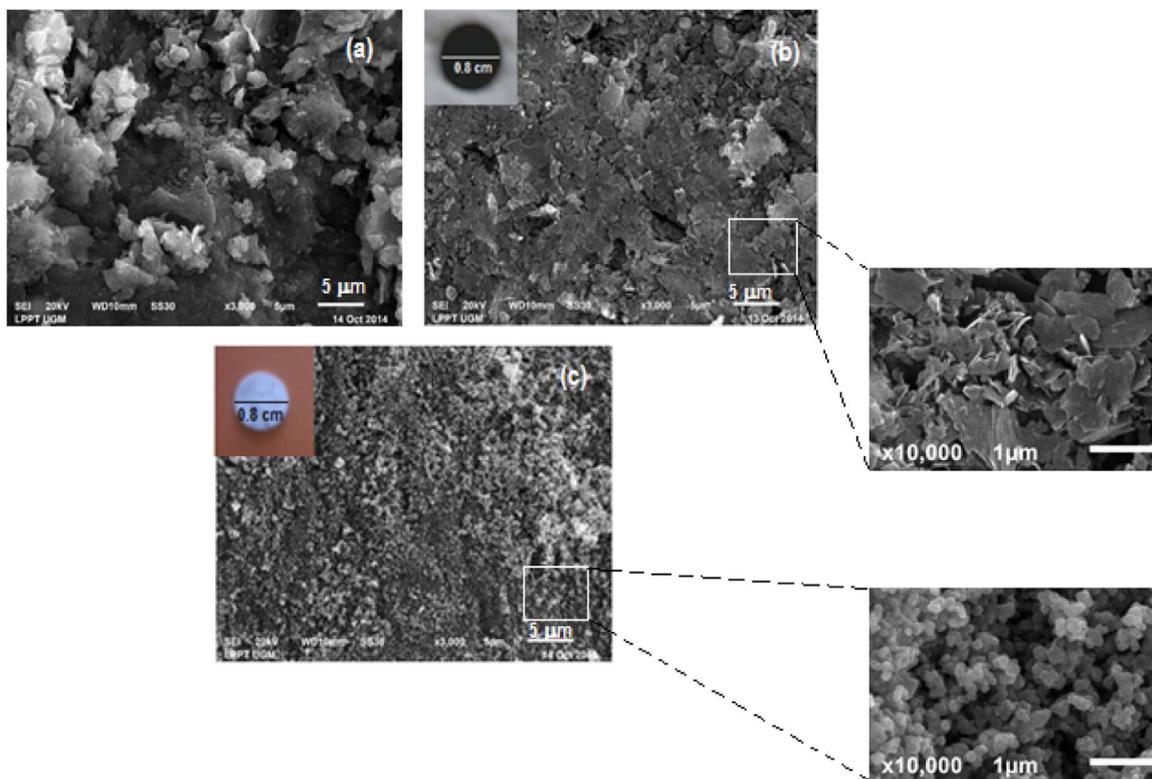

Fig. 1. SEM images of (a) graphite and (b) CdS/Graphite with CdS/Graphite photograph and the image at 10,000 magnification are inserted and (c) TiO₂/Graphite with TiO₂/Graphite photograph and the image at 10,000 magnification are inserted.

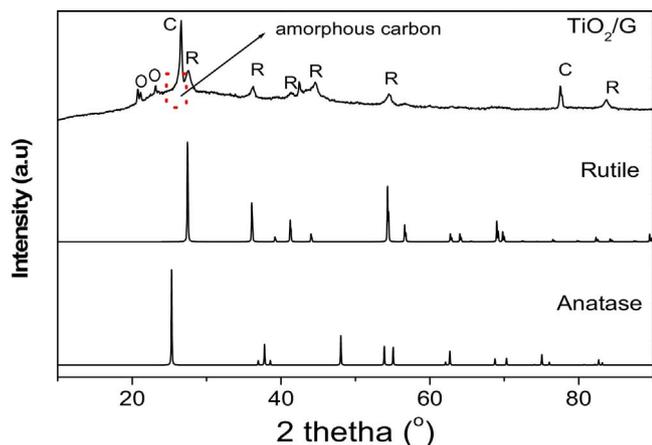

Fig. 2. The diffraction pattern of TiO₂/C and CdS/C. The TiO₂ layer consists of rutile, R, and anatase, A, phases. The O signs refer to CTAB peaks, C refers to carbon peaks.

X-ray diffraction pattern shows that TiO₂ present as rutile phase (Fig. 2), meanwhile a peak of graphitic carbon appears at 26.3°, as a strong and sharp peak of (002) plane [30]. A sharp peak at 44° also identified as graphitic carbon with (100) plane [31]. A peak at 2θ of 77.80° is identified as characteristic graphite peak based on the standard diffraction of graphite ICSD #28417. A broad peak with a width greater than 0.5°, that lying between 22 and 25° is considered as amorphous carbon [30]. Meanwhile, peaks at 2θ of 21.32° and 24.04° are CTAB peaks as confirmed by standard diffraction of JCPDS #48-2454 proof that the highest content of carbon rod waste is the carbon element supported by EDX analysis result as described in Fig. 3. The second dominant element is an oxygen atom that could be coming from graphitic oxide or other metal oxide or alkaline oxide as they were detected as trace elements (Fig. 3).

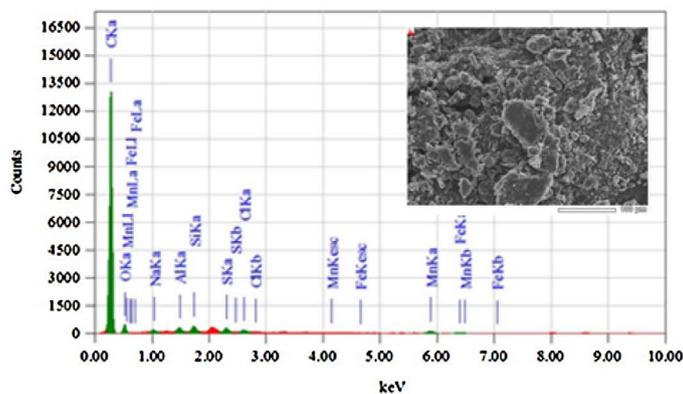

XRD pattern of CdS/C present peaks of CdS at 26.6° and a peak at 2θ

of 55° as it is confirmed by the standard diffraction of CdS ICSD# 81925 (Fig. 4). The presence of CdS also shows by EDX analysis which detected at 0.02% (Fig. 5) and also shows by elemental mapping as described in Fig. 6, that confirm the presence of CdS on the carbon substrate. Data of weight change after CdS and TiO₂ deposition are listed in Table 1. Meanwhile, the EDX result of TiO₂/C shows an incorporation of TiO₂ on carbon substrate (Fig. 7).

Tauc plot of reflectance data is in Fig. 8. The Tauc plot direct transition of CdS/C (Fig. 8(a)), shows that the gap energy of CdS/C 2.39 eV. It is in agreement with the gap energy of CdS, i.e. 2.4 eV [16]. Meanwhile, the energy gap of TiO₂/C is 3.05 eV (Fig. 8(b)). It is in agreement with the previous research and also implies that in TiO₂/C, rutile phase has a dominant role in the photocatalytic process [29].

This research tried to ensure the contribution of carbon substrate into the photo-catalytic activity of CdS film by conducting a photo-catalytic activity test to a CdS/glass and CdS/C with isopropanol molecules as the degradation target. The preparation and geometry of the CdS/glass itself were precisely similar to the CdS/C. The photo-catalytic test was conducted under UV (380 nm) and visible (450 nm) light. The results are in Fig. 9.

Fig. 9 shows that the degradation product is similar, shown by a new peak at 225–227 nm. The peak is indicated as a ketone functional group, as it was stated by Kumar (2006) [32] that ketone functional group shows an electronic transition of $\pi \rightarrow \pi^*$ at 180–195 nm. The peak will shift to longer wavelength in a more polar solvent. In this research, the solvent is water, a polar solvent, therefore the peaks are shifted to longer wavelength. When a UV wavelength of 380 nm irradiated the samples, the result shows that the degradation product is larger in the degradation system with CdS/glass as a photocatalyst, than in the system with CdS/C as a photocatalyst. It is known that silica has band gap energy, E_g of 7.7 ± 0.05 eV [33]. The value is high and requires high energy photon, at least ~ 142.5 nm to initiate an electronic transition. Therefore, when the UV light at 380 nm irradiated the CdS/glass, only CdS that undergo electron excitation, and the empty

silica glass conduction band may serve as the electron receiver and reduce the possibility of electron-hole recombination. Meanwhile, the graphite substrate with amorphous carbon content inside is known to has a peak at around 4.0–5.0 eV (Fig. 8), which correlates to the light wavelength of 310–248 nm. Those peaks may contribute to the $\pi \rightarrow \pi^*$ transition. Graphite has an aromatic hydrocarbon compound containing benzene rings in its structure with the large delocalized orbitals around the benzene rings. Some $\pi \rightarrow \pi^*$ transitions are possible from the singlet ground state to the singlet excited states. The optical absorption spectrum of graphite at visible range from 0 up to 5 eV originates from transition among π bands [34]. A calculation by Johnson and Dresselhaus [35] on the π bands in graphite, which were determined by McClure parameters along with the addition of in-plane neighbor's interactions, resulted in the allowed optical transitions near 5 eV. Interaction with CdS allows coupling mechanism that causes the absorption edge of the carbonaceous peak drop to the same point on the energy axis with the absorption edge of CdS peak (Fig. 8). Such interaction indicates that the carbonaceous substrate also active when the UV light used as a source, and it allows the conduction band of the substrate were not available to be the electrons receiver and contribute to the reducing of electron-hole recombination.

		0.087	0.091	0.004
			Average (g)	0.008 ± 0.003
2.	TiO ₂ /C	0.124	0.131	0.007
		0.118	0.127	0.009
		0.087	0.094	0.007
			Average (g)	0.008 ± 0.0005

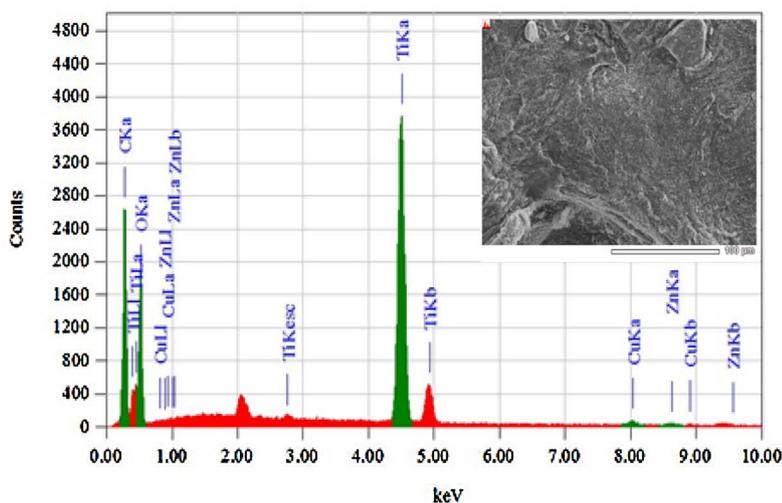

A different result shows in Fig. 9(b) when the visible light of 450 nm was used as a photon source. In fact, the photon energy is insufficient to initiate an electronic excitation in the carbonaceous substrate, and allows the substrate to become a good electron sink to reduce the possibility of electron-hole recombination. Silica glass, whether the amorphous or crystalline phase is optically transparent to the optical energy of 0–5 eV [36]. It may allow large of photon past the CdS/glass without any photocatalytic mechanism to occur. Meanwhile, the carbonaceous substrate is not transparent optically and therefore can hold the photon to stay in the material and increase the possibility to be used by CdS to excite the electrons from valence band to conduction band. Therefore, it will be an advantage for carbonaceous substrate when the degradation proceeds with visible light as energy source. In addition, carbonaceous substrate is known as a good conductor that will allows them to be used in a photo-electro-assisted degradation system.

Photocatalytic activity test on isopropanol degradation with CdS/C and TiO₂/C as a catalyst also shows a new peak at 225–227 nm (Fig. 10). The absorbance at 225–227 nm is higher when CdS/C was used as photocatalyst than the absorbance when TiO₂/C was used under both radiation of 450 nm and 380 nm. In Fig. 10(a) the absorbance of

the solution after being treated with CdS/C is over 1.0 when it was radiated by a high UV light energy. It is probably an indication of the photocatalyst layer exuviation which did not occur for TiO₂/C. The CdS exuviation is probably also occurred when the substrate is a silica glass, shown by a high absorbance over 1.0 (Fig. 9). It needs a further investigation regarding the quality of film attachment. However, this fact seems to do not affect the photocatalytic activity of the CdS/C, as it is found to be higher than TiO₂/C and the hydrogen production test also found the same conclusion. The activity is confirmed by the quantum yield, QY, values as listed in Table 2.

Under Ultraviolet radiation (380 nm), TiO₂/C has higher photon absorption in every second. However, the mole number of the product in every second (mole.s⁻¹) that is represented by absorbance value at 225–227 nm, is lower than the mole number of product in every second (mole.s⁻¹) when the photodegradation proceed with CdS/C as the photocatalyst. Therefore, the QY value as calculated by Eq. (1) of TiO₂/C is lower than CdS/C at UV light radiation. The conduction band (CB) potential of CdS which is in a higher position of carbon allows migration of the excited electrons from the conduction band of CdS to the conduction band of carbon. The CB potential of CdS is –0.52 V (vs. NHE). Meanwhile, the CB potential of graphene as an allotrope of carbon is –0.11 to (–0.30) Volt (vs. NHE) [37]. Those CB potential position is leading thermodynamically to transfer photogenerated electrons from CdS to the carbon-based substrate. The intimate contact between CdS-carbon as well as the capability of carbon on capturing electrons further reduce the recombination of photogenerated electron-hole, and degradation reaction may proceed well. The lower bandgap of CdS, 2.39 eV, seem to increase the ability of an electron to excite from valence to conduction band, in comparison to the TiO₂ case, due to the higher band gap of TiO₂, 3.05 eV. Therefore, with the same substrate that can reduce recombination phenomena, the degradation seem to proceed faster and more efficient when CdS-Carbon as a couple than TiO₂-carbon as a couple.

This research provides Quantum Yield value as the parameter for

photocatalytic activity that confirms the production of degradation resulted in a second when the catalyst received photon in every second. This QY value is reliable for analysis of a fast photocatalytic degradation process, such as in this research in which the degradation was conducted for 90 min only. Other research in isopropanol degradation

found that a further degradation occurs after the degradation proceeds for 5 h. The product of isopropanol degradation was propanone and acetaldehyde, and they undergo further degradation to CO₂. However, the CO₂ product was found only in a gas- solid system, in which the isopropanol to be degraded is in a gas phase. Further degradation to

Table 2

Quantum Yield of CdS/C and TiO₂/C at a various wavelength of radiation light for isopropanol degradation.

Materials	Wavelength (nm)	N _{mol} (mol/s)	N _{photon} (mol photon/s)	Quantum Yield	Relative QY
CdS/C	380	5.302×10^{-5}	3.21×10^{-2}	1.651×10^{-3}	11.05
	450	5.299×10^{-5}	5.89×10^{-2}	9.004×10^{-4}	6.03
	517	3.227×10^{-5}	5.89×10^{-2}	5.478×10^{-4}	3.67
TiO ₂ /C	380	3.303×10^{-5}	2.21×10^{-1}	1.495×10^{-4}	1.00
	450	0	4.23×10^{-4}	0	0

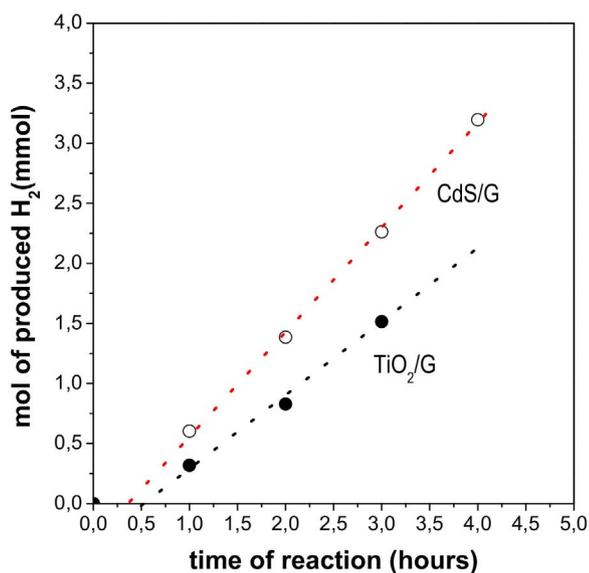

Fig. 11. The quantity of hydrogen production with CdS/C and TiO₂/C as photocatalyst.

CO₂ does not occur for the liquid-solid system [38].

A higher photocatalytic activity also occurred under visible light radiation. In which, it is clear that TiO₂ with high energy band gap, 3.05 eV, is not active in visible light because the energy of a photon is not sufficient to excite the electrons from valence band to conduction band. Even though, the photons were absorbed, as can be seen in Table 2. However, the photon is not active photo-catalytically. Instead of the TiO₂ layer, the carbon or graphitic carbon itself can absorb light and use it for $\pi \rightarrow \pi^*$ transition [35]. Therefore, the number of photon absorption might also serve as a contribution of the carbon substrate.

In term of photocatalytic activity for H₂ production, the hydrogen production rate with CdS/C is 1.67 times higher than the H₂ production rate with TiO₂/Graphite. The hydrogen production rate with CdS/C is $0.369 \mu\text{mol s}^{-1} \text{g}^{-1}$. Meanwhile, the rate with TiO₂/C is $0.222 \mu\text{mol s}^{-1} \text{g}^{-1}$. The curve of H₂ production with CdS/C and TiO₂/C are described in Fig. 11. The remarkable CdS performance also found when the nanotube TiO₂ (TiO₂NTs) was incorporated by CdS nanoparticle [23]. Meanwhile, photocatalytic hydrogen production with

TiO₂ P25 powder produces rate of $3.04 \mu\text{mol s}^{-1} \text{g}^{-1}$ [1]. CdS can serve as a photosensitizer and the active photocatalyst itself. The mercury lamp that was used in this hydrogen production has a wavelength range between visible – ultraviolet light. The lines are 184.45 nm (UV-C), 253.7 (UV-C), 365.4 (UV-A), 404.7, 435.8, 546.1, and 578.2 (visible light). The CdS/C is known to active under ultraviolet and visible light (450 nm–517 nm) with QY values larger than TiO₂/C on that two kinds of light.

4. Conclusion

CdS/C has a higher photocatalytic activity that allows higher H₂ production than TiO₂/C whether under UV or visible light radiation. The QY value of CdS/C under UV light of 380 nm is 1.651×10^{-3} . It is 11.05 times of QY of TiO₂/C, i.e. 1.495×10^{-4} . Meanwhile, under visible light radiation, CdS/C shows photocatalytic activity with QY of 9.004×10^{-4} , in which TiO₂/C is inactive. The hydrogen production rate with CdS/C is 1.67 times higher than the H₂ production rate with TiO₂/C. The hydrogen production rate with CdS/C is $0.369 \mu\text{mol s}^{-1} \text{g}^{-1}$. Meanwhile, the rate with TiO₂/C is $0.222 \mu\text{mol s}^{-1} \text{g}^{-1}$.
