Dear Dr. Daniel Ginting

We recently received Manuscript ID SO-21-2967 entitled "How does the knowledge of renewable energy affect college students' energy-saving intentions? -- Evidence from China" and, based on your area of expertise, would like to invite you to review this manuscript. The abstract appears at the end of this letter.

SAGE Open (IF 1.356) is an open access, peer-reviewed journal indexed in Sciences Citation Index (SSCI), DOAJ (Directory of Open Access Journals), and Scopus which focuses on Humanities, Social Sciences, and Behavioral Sciences.

Should you accept our invitation, we would ask that you complete your review by 06-Feb-2022. We realize you must have a number of personal and professional priorities at the moment, given the global situation around COVID-19. If you are not able to review at this time or you need additional time to complete this review, please let us know. Your safety and that of your family is our priority during these difficult times. You may e-mail me with your reply or click the appropriate link at the bottom of the page.

As a member of The Committee on Publication Ethics (COPE), SAGE Open is committed to ensuring that the peer-review process is as robust and ethical as possible. We encourage you to read the [COPE guidelines here](#) and make use of [SAGE Open's own guides for reviewers here](#).

SAGE Open values the work of our reviewers. In recognition of your support, we are pleased to offer you free access to all SAGE journals for 60 days upon receipt of your completed review and a 25% book discount on all SAGE books ordered online. We will send you details of how to register for online access and order books at discount as soon as you have submitted your review.

Our reviewers now have the opportunity to opt-in to receive credit for their review contributions at Publons.com. You can read more about opting in and how this benefits you here: <https://publons.com/in/sage/>

If you accept our invitation to review this manuscript, you will be notified via e-mail about how to access Manuscript Central, our online manuscript submission and review system. You will then have access to the manuscript and further reviewer instructions in your Reviewer Center.

Expert reviewers greatly contribute to the high standards of our journal, and I thank you for your present and/or future participation.

Sincerely,  
Simran Bhambri

## MANUSCRIPT DETAILS

**TITLE:** How does the knowledge of renewable energy affect college students' energy-saving intentions? -- Evidence from China

**ABSTRACT:** Renewable energy and its related technologies can alleviate the energy problems human beings face. Therefore, after gaining knowledge of renewable energy, do college students believe that the energy problem has been or can be solved, thus reducing their own energy-saving intentions? To answer this question, the present study conducted a field survey of college students in Xi'an, China, employing structural equation modeling to analyze college students' knowledge of renewable energy and the impact of it on energy-saving intentions. The study sought to identify the influencing factors and their influencing paths on college students' energy-saving intentions. This study also explored how the knowledge of renewable energy affects college students' energy-saving intentions through value perception. The main conclusions are as follows: (1) knowledge of renewable energy has a positive impact on college students' energy-saving intentions; (2) this impact is mainly realized through college students' value perception of energy saving; (3) knowledge of renewable energy mobilizes college students to evaluate the benefits of energy saving, which is the key to enhancing their energy-saving intentions; and (4) the impact of knowledge about renewable energy on personal norms is stronger than that on perceived value.

## Confidential Comments to the Editor

This paper has a robust methodology. The authors have explained the research design well. In addition, they justify the quality of the instrument, show clear data collection procedures, and even present research results in a structured manner.

The authors also have interesting conclusions: Knowledge of renewable energy positively impacts college students' energy saving intentions; (2) The impact is mainly realized through college students' perceived value (PV) of energy saving. (3) Knowledge of renewable energy mobilizes college students to evaluate the benefits of energy conservation, which is the key to enhancing their energy-saving intentions; and (4) The impact of the knowledge of renewable energy on personal norms is stronger than that on perceived value.

The authors have justified the causal explanation through theoretical triangulation (previous study). I appreciate that. However, I do not see how the authors relate the results of their research to other important factors such as cultural and demographic factors. Whereas empirically, these two factors are very influential on how people think, behave, and perceive anything in life.

## Comments to the Author

This paper has a robust methodology. The authors have explained the research design well. In addition, they justify the quality of the instrument, show clear data collection procedures, and even present research results in a structured manner.

The authors also have interesting conclusions: Knowledge of renewable energy positively impacts college students' energy saving intentions; (2) The impact is mainly realized through college students' perceived value

(PV) of energy saving. (3) Knowledge of renewable energy mobilizes college students to evaluate the benefits of energy conservation, which is the key to enhancing their energy-saving intentions; and (4) The impact of the knowledge of renewable energy on personal norms is stronger than that on perceived value.

The authors have justified the causal explanation through theoretical triangulation (previous study). I appreciate that. However, I do not see how the authors relate the results of their research to other important factors such as cultural and demographic factors. Whereas empirically, these two factors are crucial and very influential on how people think, behave, and perceive anything in life.

**Key words:** energy-saving intention; knowledge of renewable energy; college students; perceived value

## 1 Introduction

1  
2  
3  
4 Buildings are important energy end-users, demanding around 3060 Mtoe each year,  
5  
6 which in 2018 accounts for 36% of final global energy consumption and 28% of energy-  
7  
8 related CO<sub>2</sub> emissions worldwide [1]. According to the Intergovernmental Panel on  
9  
10 Climate Change, energy consumption of college buildings accounts for a large part of  
11  
12 the total global energy consumption [2, 3]. The number of campus buildings in China  
13  
14 accounts for only 3%–7% of the total number of urban buildings. However, the energy  
15  
16 consumption of campus buildings accounts for 30% of the total energy consumption of  
17  
18 all buildings, and the energy consumption per unit area of colleges is 5-10 times higher  
19  
20 than that of ordinary residential buildings [4-6]. Moreover, the per capita energy  
21  
22 consumption of Chinese universities is four times that of the entire country [7, 8]. This  
23  
24 data makes clear that colleges need to bear the high cost of energy consumption and  
25  
26 demonstrates that to realize carbon reduction and carbon neutrality, the focus needs to  
27  
28 be on universities and on college students.  
29  
30  
31  
32  
33  
34  
35  
36  
37

38 Knowledge is one of the key factors that affects the intentions and behaviors  
39  
40 related to energy-saving [9, 10]. College students are exposed to many types of  
41  
42 knowledge, including of renewable energy, through learning, communication with  
43  
44 classmates or teachers and through social networks. Renewable energy is a kind of  
45  
46 energy that can be recycled and regularly supplemented or reused in nature. In recent  
47  
48 years, the development of renewable energy has alleviated many energy problems and  
49  
50 is an important means to adjust the energy structure [11]. When there is a certain  
51  
52 cognition or stereotype, people's attitude will also change [12]. The emergence of  
53  
54 renewable energy and related technologies may lead college students to believe that the  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 energy problem is not serious. Therefore, we have reason to suspect that college  
5  
6 students will change their perception and understanding of energy issues by learning or  
7  
8 gaining contacting with relevant knowledge about renewable energy. If college students  
9  
10 change their understanding of energy issues, their energy-saving intentions may also  
11  
12 change. When college students realize that the energy problem can be solved by the  
13  
14 development of renewable energy, they may develop a negative stereotype of energy-  
15  
16 saving; if this type of knowledge indeed has a negative impact on energy-saving  
17  
18 intentions, it is necessary to consider strategies and supporting measures for teaching  
19  
20 in the future. The existing literature does not fully reveal how knowledge of renewable  
21  
22 energy affects college students' energy-saving intentions. There are two reasons for this:  
23  
24 first, whether knowledge has a positive or negative impact on energy-saving intentions  
25  
26 remains controversial [13]; second, the mechanism of knowledge on energy-saving  
27  
28 intentions has yet to be adequately studied [14].  
29  
30  
31  
32  
33  
34  
35  
36

37  
38 The main reason behind the first point is that there exist different types of  
39  
40 knowledge, and different types of knowledge may impose different influences on  
41  
42 energy-saving intentions. For example, knowledge about the progress of energy-saving  
43  
44 technology, including energy-saving products [15] and the standard of energy  
45  
46 consumption of electrical appliances [16], has a negative impact on energy-saving  
47  
48 intentions. However, a background knowledge of the ecological environment and  
49  
50 energy utilization and knowledge of personal energy-saving skills typically have a  
51  
52 positive impact on energy-saving. The back ground knowledge include environmental  
53  
54 concern [17] and understanding of climate change and environmental issues [18]. The  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 knowledge of personal energy-saving skills include knowledge of household energy-  
5  
6 saving skills <sup>[19]</sup> and of specific measures that reduce carbon dioxide emissions <sup>[20]</sup>.  
7  
8  
9 Knowledge about renewable energy can on one hand attribute of the advanced energy-  
10  
11 saving technology; on the other hand, textbooks and classes about renewable energy  
12  
13 may involve a background knowledge of environment and energy. Therefore, it is  
14  
15 difficult to directly judge whether the impact of a knowledge about renewable energy  
16  
17 is positive or negative.  
18  
19  
20

21  
22       Regarding the second point, a study on people's behaviors in buildings has  
23  
24 summarized the existing research on energy-related behaviors and listed the relevant  
25  
26 factors that influence energy-saving intentions <sup>[10]</sup>. Among these factors, attitude  
27  
28 (especially perceived value) and norms are obviously affected by knowledge; however,  
29  
30 current research on the relationship between knowledge and energy-saving intentions  
31  
32 focuses only on whether a certain type of knowledge affects energy saving <sup>[19, 21, 22]</sup>, or  
33  
34 simply that knowledge is one of the direct influencing factors <sup>[23, 24]</sup>. Unfortunately, few  
35  
36 studies focus on the process or relationship of "knowledge-perceived value/norm-  
37  
38 intention."  
39  
40  
41  
42  
43  
44

45       This paper will focus on solving the following problems and put forward  
46  
47 suggestions according to the research results, so as to better guide practice:  
48  
49

50       1. whether the knowledge of renewable energy reduces college students' energy-  
51  
52 saving intentions;  
53

54       2. whether the knowledge of renewable energy affects college students' energy-  
55  
56 saving intentions through an impact on the perception of the value of energy-saving;  
57  
58  
59  
60

1  
2  
3  
4 3. whether personal norms or perceived value plays a more important role in the  
5  
6 process.  
7  
8

## 9 **2 Literature reviewed and hypothesis postulate**

### 10 **2.1 Influence factors of energy-saving intention**

11  
12  
13  
14 Theory of Planned Behavior (TPB) is widely used to study environmental  
15 behaviors and intentions [10]. The core view of it is that intention is directly affected by  
16 attitude, subjective norms and perceived behavior control [25]. The purpose of this study  
17 is to explore whether and how knowledge affects energy-saving intentions; therefore,  
18 on the basis of TPB, this paper sets perceived value of energy saving and personal  
19 norms as the direct influence factors. The reasons are as follows.  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29

30 First, attitude in TPB refers to the cognition of behavior and its consequences [10],  
31 and knowledge is a factor influencing this cognition [26]. Since one key goal of this  
32 paper is to explore how the knowledge of renewable energy affects energy-saving  
33 intentions, the mechanism of knowledge on attitude is analyzed (see Section 2.2 for  
34 details). Based on this and according to the definition of attitude, we specifically study  
35 one of the elements of attitude, that is, the perceived value of energy saving. The  
36 relationship between perceived value and energy-saving intentions should prove similar  
37 to the relationship between attitude and intention in TPB [27]. As such, Hypothesis 1 is  
38 put forward as the following: H1: Perceived value (PV) has a positive impact on energy-  
39 saving intentions (INT).  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54

55 Second, in recent years, research on energy saving and norms has divided norms  
56 into subjective norms [28], descriptive norms (Ding et al., 2019 and personal norms [29].  
57  
58  
59  
60

1  
2  
3  
4 Subjective norms refer to the social pressures on individuals when they carry out their  
5  
6 behaviors; descriptive norms refer to how to carry norms out in a specific situation.  
7  
8  
9 Neither is directly related to knowledge. Personal norms, defined as the moral  
10  
11 obligation to fulfill or not perform a particular act <sup>[30]</sup>, are mainly about personal  
12  
13 knowledge rather than about external pressure. Therefore, this paper replaces the  
14  
15 subjective norms in TPB with personal norms, and assumes that they exert a positive  
16  
17 impact on energy-saving intentions. Hypothesis 2 thus reads as follows: H2: Personal  
18  
19 norms (PN) have a positive impact on INT.  
20  
21  
22  
23  
24

25 Third, perceived behavior control mainly refers to the expectation of resources and  
26  
27 obstacles related to the implementation of behavior. This factor is not directly related  
28  
29 to knowledge, therefore we do not consider the influence of this factor on this study's  
30  
31 target problems.  
32  
33  
34

## 35 **2.2 Influence factors of perceived value**

36  
37 The concept of perceived value originally refers to consumers' perceived  
38  
39 preference and evaluation of products; it affects the whole process of consumers'  
40  
41 perception, evaluation and purchase of product value <sup>[31]</sup>. On the basis of this concept,  
42  
43 scholars have put forward the concept of green perceived value, which refers to  
44  
45 consumers' overall assessment of the net income of a product or service based on  
46  
47 environmental aspirations and expectations of sustainability <sup>[32]</sup>. In recent years, the  
48  
49 concept of perceived value has been used to study issues surrounding the environment  
50  
51 and energy saving <sup>[27, 33]</sup>. This paper relies on this concept to describe college students'  
52  
53 overall evaluation of the net income of energy saving.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 In recent years, research on perceived value and energy saving or environmental  
5  
6 intention suggests that perceived value can be further subdivided <sup>[34]</sup>, such as perceived  
7  
8 quality, perceived price and emotional and environmental values. These factors will  
9  
10 significantly positively affect consumers' purchase intention for energy-saving devices  
11  
12 <sup>[35]</sup>. Some studies divide the factors that affect perceived value into perceived benefits  
13  
14 and perceived sacrifices, that is, the cost of implementing green consumption.  
15  
16 Moreover, perceived benefit is positively correlated with green consumption intention,  
17  
18 while perceived sacrifice is negatively correlated with it <sup>[36]</sup>. Some scholars found that  
19  
20 perceived value is affected by perceived benefit and perceived risk and that perceived  
21  
22 benefit is affected by knowledge <sup>[15]</sup>. Wang also proposed that knowledge will  
23  
24 positively affect perceived value <sup>[9]</sup>. Based on the references cited above, this paper sets  
25  
26 three influencing factors of perceived value: perceived benefit (PB), perceived costs  
27  
28 (the cost of implementing energy-saving behaviors, abbreviated as PC) and perceived  
29  
30 risk of non-implementation of energy saving (PR). We also assume that there is  
31  
32 interaction among the three factors. In addition, it is necessary to assume that  
33  
34 knowledge of renewable energy has an impact on these three factors. We believe that  
35  
36 knowledge of renewable energy points out that the energy problem can be and is being  
37  
38 solved, so it will lead to negative energy-saving intentions. As Sun pointed out, the  
39  
40 more people understand the performance of energy-saving products, the less willing  
41  
42 they are to save energy <sup>[16]</sup>. To sum up, the assumptions in this part are as follows:

43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56 H3a: PB has a positive impact on PV;

57  
58  
59  
60  
H3b: PC has a negative impact on PV;

---

H3c: PR has a positive impact on PV;

H4a: PC has a negative impact on PB;

H4b: PR has a positive impact on PB;

H5a: Knowledge of renewable energy (KRE) has a negative impact on PB;

K5b: KRE has a negative impact on PR;

H5c: KRE has a positive impact on PC.

### **2.3 Influence factors of personal norm**

At present, relevant studies suggest that personal norms are influenced by attitude, consequence, responsibility [37, 38], environmental concern and perceived consumer effect [29]. Since this paper has expressed attitude and the consequences of it with perceived value and its influencing factors, it is assumed that perceived value will affect personal norms, which is similar to the view that norms and attitude will interact with intention [28]. In addition, because personal norms reflect the understanding of energy saving among college students, this paper also assumes that knowledge of renewable energy will make college students think that energy problems have been gradually solved, thus they do not need to save energy. Knowledge of renewable energy will therefore negatively affect personal norms. Hypotheses 6 and 7 are as follows:

H6: PV has a positive impact on PN;

H7: KRE has a negative impact on PN.

According to the above assumptions, we established a structural model as shown in Figure 1.

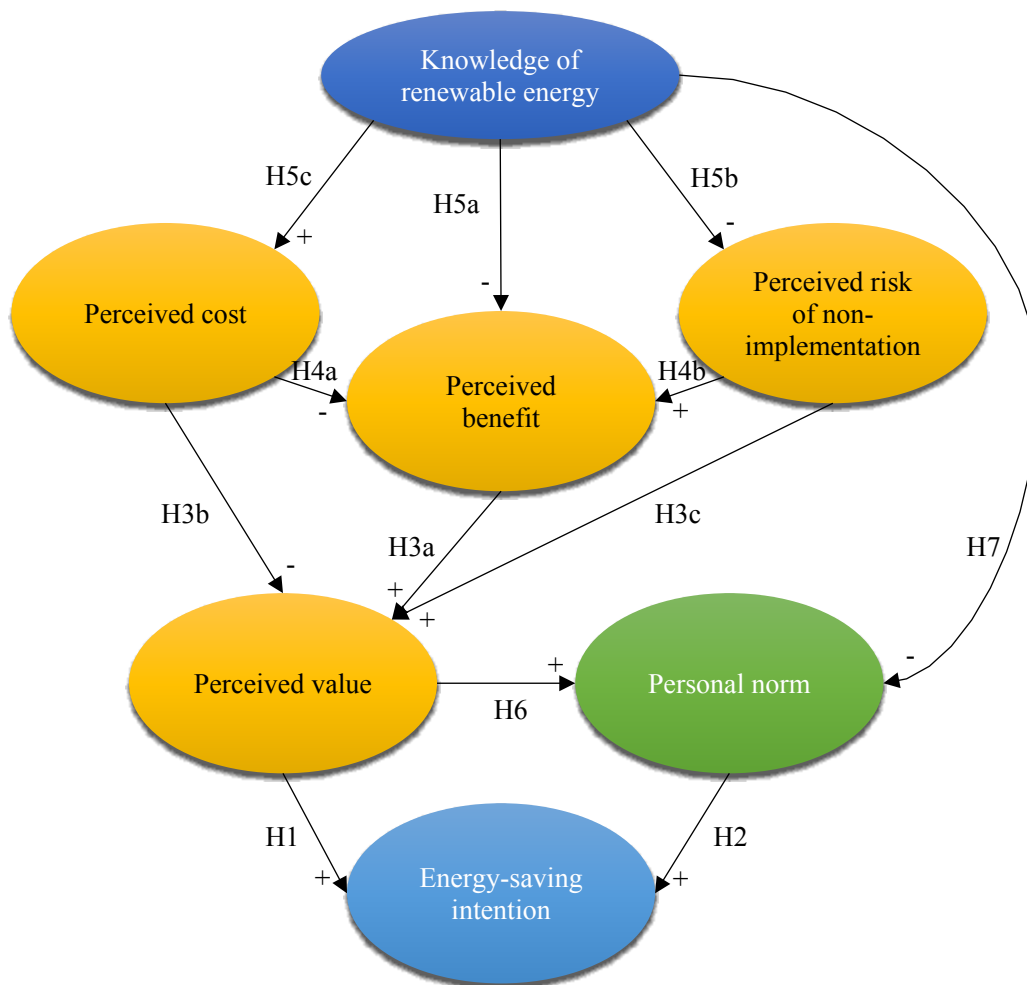

Figure 1. Structural model of the research

### 3 Methodology

#### 3.1. Questionnaire and data source

The measurement items employed in this paper include energy-saving intentions, personal norms, perceived value, perceived benefit, perceived cost, perceived risk of non-implementation and knowledge of renewable energy. On the basis of reference to relevant research [39, 15, 29], questionnaire items were designed, as shown in Table 1. For all measurement items, a five-point scale was used to indicate the extent to which respondents approve of these items, where 5 represents the most agreement and 1 represents the most disagreement. Three procedures were implemented to improve the

questionnaire and in turn to improve the accuracy of measurement. First, a Chinese sentence was designed for each item based on previous research. Second, and pre-investigation, four classes of students in the school of the researcher were selected to fill out the questionnaire (127 valid questionnaires were collected) in order to identify and then modify any problems in the questionnaire. Third, a team of four teachers and five graduate students were invited to examine the questionnaire to ensure that it was easy to read and understand so that high-quality data could be collected.

**Table 1. Questionnaire items employed in the main survey**

Factors	Items	Explanation
Energy saving intention (INT)	INT1	I'm willing to participate in energy saving.
	INT2	I'm willing to try my best to save energy.
	INT3	I'm willing to make specific energy-saving behaviors.
	INT4	I'm willing to frequently implement energy-saving behaviors.
Perceived value (PV)	PV1	My energy-saving behavior is worth it.
	PV2	It makes sense for me to save energy.
	PV3	Energy saving is a valuable behavior.
Perceived benefits (PB)	PB1	I think saving energy is good for the development of the school.
	PB2	I think saving energy is good for society.
	PB3	I think saving energy is conducive to the sustainable development of our country.
	PB4	I think saving energy is good for the future ecological environment.
Perceived cost	PC1	Energy saving interrupts what I'm doing.

---

---

	(PC)	PC2	Energy saving is a waste of time.
		PC3	I need to constantly remind myself to implement energy-saving behavior.
		PC4	Energy saving will sacrifice my study and life experience.
	Perceived risk	PR1	If I don't save energy, I may face environmental pollution.
	of non-		If I don't save energy, people around me may think my habits are not
	implementation	PR2	good.
	(PR)	PR3	If I don't save energy, I may face energy shortage.
		PN1	It is necessary for me to form the habit of saving energy.
		PN2	It is necessary for me to maintain the habit of saving energy.
	Personal norm	PN3	It is necessary to be an energy-saving person.
	(PN)		I have a responsibility to save energy for the sustainable development of
		PN4	our country.
		KRE1	I learned a lot about renewable energy from school learning.
	Knowledge of	KRE2	I learned a lot about renewable energy from social media.
	renewable	KRE3	I learned a lot about renewable energy from people around me.
	energy (KRE)		I learned a lot about renewable energy from school and social advocacy
		KRE4	activities.

---

To ensure the quality of the survey, the questionnaire was distributed to students of a university in Xi'an between April and May 2021. Some classrooms were randomly selected and those students completed a questionnaire survey while on a break to ensure the identity of the respondents and the quality of the survey. Each respondent was informed of the purpose of the investigation and the anonymity of the questionnaire.

1  
2  
3  
4 From the survey, we received a total of 473 responses, of which 401 were deemed valid.  
5  
6 Among them, male students accounted for 44.39%; female students for 55.61%;  
7  
8 students with less than one year remaining in school for 14.46%; 46.38% had one to  
9  
10 two years left; 24.64% had two to three years remaining; and 14.21% had three to four  
11  
12 years. Among all the students polled, 61.85% focused on the curriculum, 19.7% focused  
13  
14 on self-study, 15.96% were devoted to scientific research and 2.5% focused on  
15  
16 internship. Data sources show that the survey covers different types of college students,  
17  
18 therefore the sociodemographic diversity of data sources was ensured.

### 25 **3.2. Structural Equation Modeling**

26  
27 The data analysis of this study was conducted using the Structural Equation  
28  
29 Modeling (SEM) technique and followed the two-step approach for assessing the  
30  
31 measurement and structural models, respectively [40]. SEM technique is a commonly  
32  
33 used method to test relationships between constructs based on their assigned indicators  
34  
35 [41]. SEM is a powerful statistical research technique and is effective in analyzing  
36  
37 relationships between multiple-item constructs [42]. In this study, we first used SEM to  
38  
39 verify the hypotheses and structural model, and then used the bootstrap method [43] to  
40  
41 test the indirect effect of some variables.  
42  
43  
44  
45  
46  
47

## 48 **4 Results analysis**

### 49 **4.1 Structural equation model examination**

50  
51 First, confirmatory factor analysis (CFA) was employed to evaluate the reliability  
52  
53 and validity of the model. Convergent validity and composite reliability evaluate the  
54  
55 correlation between the items within the latent variables. According to related research,  
56  
57  
58  
59  
60

Cronbach's alpha and composite reliability should be greater than 0.7, and the lowest average variance extracted (AVE) should be greater than 0.5 [44, 45]. The relevant indicators of this study are shown in Table 2, and the results show that all measurement items have robust convergent validity.

**Table 2. Results of measurement model analysis**

Factors	Cronbach's Alpha	AVE	Composite reliability
INT	0.965	0.874	0.965
PV	0.936	0.826	0.935
PN	0.940	0.801	0.941
PB	0.929	0.774	0.932
PC	0.883	0.658	0.885
PR	0.794	0.583	0.804
KRE	0.837	0.567	0.838

401 samples were used to test the structural model, and the p value of some path coefficients is not significant (see Table 4 for details). Therefore, we modified the model and deleted these paths. The value of the fitting indicators and the judgment standard [46-48] of the modified model are shown in Table 3 and show that the overall fit of the structural model is good and that the modified structural model is acceptable.

**Table 3. Fit indices of the models**

Types of indicators	Statistics of goodness-of-fit	Standard values	Test values	Adaptability of the model
Absolute	CMIN/DF	< 3.00	2.301	Qualified

goodness-of-fit	CMIN	$P < 0.05$	$P = 0.000$	Qualified
	RMSEA	$< 0.08$	0.057	Qualified
	CFI	$> 0.90$	0.959	Qualified
Added-value	NFI	$> 0.90$	0.929	Qualified
goodness-of-fit	IFI	$> 0.90$	0.959	Qualified
	RFI	$> 0.90$	0.921	Qualified
Concise	PNFI	$> 0.50$	0.829	Qualified
	PCFI	$> 0.50$	0.855	Qualified
goodness-of-fit	CN	$> 200$	210	Qualified

The path coefficient of the modified model and its related test indicators are shown in Figure 2 and Table 4. The factor loads of all latent variables are not less than 0.5, which indicates that the model is more accurate in measuring factors. The standardized regression coefficients and their test results of each path in Table 4 show that the C.R. value of path coefficients of H3b, H3c and H5b falls in the interval (- 1.8, 1.8), and the p value of them are greater than 0.05. Therefore, the three hypotheses above are negated, and we deleted the corresponding three paths in the structural model. The paths corresponding to the other hypotheses are highly significant, and these hypotheses have been verified.

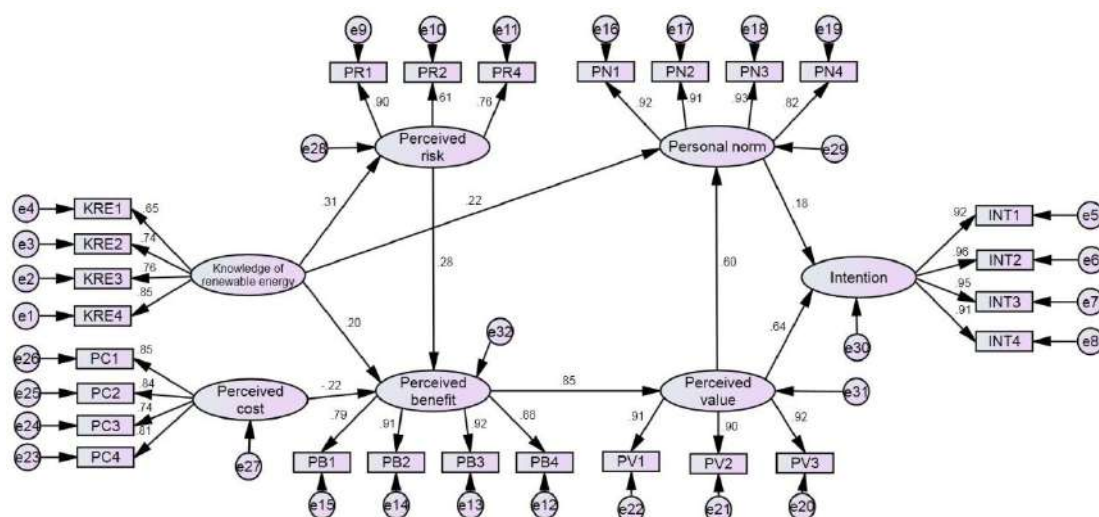

Figure 2. Testing results of the research model

Table 4. Path coefficient estimation of the model

Paths	Standardized			Hypotheses	Results
	regression weights	S.E.	C.R.		
KRE→PC	-0.025	0.066	-0.399	H5c	Not supported
PC→PV	-0.066	-1.798	0.072	H3b	Not supported

KRE→PR	0.307	0.063	5.321***	H5b	Not supported

PV→PN	0.601	0.043	13.363***	H6	Supported
KRE→PN	0.215	0.039	4.824***	H7	Not supported

Note: \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ .

#### 4.2 Direct effect

First, the direct effect of KRE is the most inconsistent with our expectation. The path coefficients corresponding to H5a, H5b and H7 are positive, which indicates that KRE has a positive effect on PB, PR and PN. The results contradict the hypothesis of negative effect. Therefore, H5a, H5b and H7 are negated, but the result proves the actual situation is contrary to the hypothesis. These results show that knowledge of renewable energy does not weaken college students' cognition that energy saving is valuable, as we previously thought; on the contrary, it even enhances this cognition. Second, PB is a key factor in the process of college students' perception of the value of energy saving. PC and PR have no significant direct effect on PV, while PB has significant direct effect on PV. In addition, the path coefficient of PB to PV is 0.847, and the high value shows that the relationship between them is quite close. Once college students consider that energy saving will bring benefits, they obviously tend to believe that energy saving is valuable. The significant direct effect of KRE on PB indicates that knowledge of renewable energy has a positive effect on improving college students' perception of energy saving. Third, for college students' energy-saving intentions, PV poses obvious importance. The path coefficient of PV to INT is 0.636, which is significantly higher than that of PN to INT (0.179). This result shows that college students are more concerned about the value of energy saving than whether they should

carry out energy-saving behaviors. In addition, the path coefficient of PV to PN is 0.601, and the high value indicates that college students' personal norms for energy saving will also be greatly affected by PV. This result shows the great influence of PV in energy-saving intentions from another perspective.

### 4.3 Indirect effect

The above test and analysis verified the direct effect between the variables. However, due to the complexity of the structural model, there are some intermediate variables among some variables. For example, KRE does not directly affect PBs; it may only affect PV, but does not affect INT through PV. Therefore, to clarify the mechanism of KRE on college students' energy-saving intentions, we need to test whether there are indirect effects among several key variables. The bootstrap method was used to test the indirect effect of some variables. We chose to repeat 5000 times, deciding the existence of indirect effects according to whether the indirect effect includes 0 in the 95% confidence interval. The results are shown in Table 5.

**Table 5. Results of mediation effect analysis**

		95% confidence intervals			
IV	DV	Indirect effect	lower limit	upper limit	
PC	PV	-0.190	-0.304	-0.078	
PR	PV	0.234	0.121	0.343	
KRE	PV	0.241	0.148	0.332	
KRE	PN	0.145	0.077	0.216	
KRE	INT	0.218	0.140	0.300	

PV	INT	0.108	0.043	0.201
----	-----	-------	-------	-------

There is a significant indirect effect between the tested variables because there is no 0 in the 95% confidence interval. The indirect effect of KRE on PV, PN and INT is significant, and the standardized indirect effect value is between 0.145 and 0.241, which indicates that the indirect effect of KRE is obvious in the formation process of college students' energy-saving intentions. In other words, KRE not only directly affects college students' perception of the cost, benefit and risk of non-implementation of energy saving, but also affects their personal norms and intention to save energy through these perceptions. The influence of KRE on the formation of college students' energy-saving intentions is continuous. For the same reason, PC and PR also affect PV through PB. Combined with the verification results of H3b and H3c, the mechanism of PC and PR on PV is indirect rather than direct, and the mediating variable is PB. The total effect of PV on INT is 0.744. This result shows that PV plays an important role in the formation of college students' energy-saving intentions. In addition, the total effect of KRE on PN is 0.360, which is larger than its indirect effect on PV, indicating that KRE mainly affects college students' energy-saving intentions through PN.

## 5 Discussion

### 5.1 Impact of the knowledge of renewable energy

First, the results show that the path coefficients associated with KRE are all positive, assuming that H5a, H5b and H7 are negated. That is, the impact of KRE to PV and PN is positive. In the hypotheses part, we assumed that KRE would lead college students toward a positive expectation of energy, therefore they will believe that current

1  
2  
3  
4 energy saving efforts are unnecessary and then reduce the PV. However, the results  
5  
6 show that KRE improves college students' PV through PB, PR and PN. In order to  
7  
8 understand the meaning of the results, we further considered previous studies.  
9  
10 Literature that considers that knowledge has a negative impact on energy-saving  
11  
12 behaviors or intentions usually investigates knowledge about the energy-saving  
13  
14 performance of energy-saving products and equipment, such as electricity consumption  
15  
16 of energy-saving lamps, the stand-by energy consumption of electrical appliances <sup>[16]</sup>  
17  
18 or understanding of energy-saving products <sup>[15]</sup>. The knowledge of specific energy-  
19  
20 saving products may make residents believe that energy saving has been realized by  
21  
22 technology and products, so their energy-saving behavior is not of great value. This is  
23  
24 also the core idea of hypotheses H5a, H5b and H7. However, other studies report that  
25  
26 knowledge has a positive impact on energy-saving behavior or willingness; most of  
27  
28 these studies investigate macro or holistic knowledge about the ecological environment  
29  
30 and energy consumption. For example, incorrect understanding of energy issues is not  
31  
32 conducive to energy conservation <sup>[49]</sup>, and understanding of the environment and carbon  
33  
34 dioxide emissions is conducive to energy saving <sup>[20]</sup>. Considering the results of the  
35  
36 above two types of studies, we believe that in the process of learning about renewable  
37  
38 energy, college students gain background knowledge related to the environment, energy  
39  
40 constraints and carbon dioxide emissions, which enhances their intentions to save  
41  
42 energy. However, although the knowledge of renewable energy makes college students  
43  
44 realize that the energy problem can be solved, that problem has not yet been completely  
45  
46 solved, which stimulates college students' PV of energy saving. Therefore, in the future,  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 the teaching of renewable energy in colleges should be comprehensive and systematic.  
5  
6 It is important to avoid the simple propaganda of technological progress, and  
7  
8 supplementing background knowledge about energy and the bottleneck of renewable  
9  
10 energy is necessary.  
11  
12

13  
14 In addition, H5c is negated, and the actual situation is that the influence of KRE  
15  
16 on PC is not significant. KRE has not made college students feel that it is troublesome  
17  
18 and laborious to implement energy-saving behaviors. Combined with the positive  
19  
20 influence of KRE on PR and PB and its discussion, this phenomenon is not difficult to  
21  
22 understand. Meanwhile, KRE has no negative impact on PC. There may be two reasons  
23  
24 for this result. First, the content of KRE does not involve the daily energy-saving  
25  
26 behavior of college students. Second, the evaluation of the cost of energy saving is  
27  
28 relatively independent; therefore, even though KRE improves the understanding of  
29  
30 energy saving of college students, the negative emotions of students in implementing  
31  
32 energy-saving behaviors still needs to be considered.  
33  
34  
35  
36  
37  
38  
39

## 40 **5.2 About perceived value**

41  
42  
43 The central element of Prospect Theory is loss aversion, which describes the  
44  
45 observation that losses have a relatively larger impact on observed decisions than gains,  
46  
47 relative to a subjective reference point [50, 51]. According to this theory, PC and PR  
48  
49 should have a greater impact on the judgment of the value of energy saving than PB. In  
50  
51 recent years, studies on the application intention of energy-saving technology and  
52  
53 equipment also show that loss and risk-averse groups are less willing to engage with  
54  
55 energy-efficient appliances or technologies [52, 53]. However, the results of this paper  
56  
57  
58  
59  
60

1  
2  
3  
4 reject H3b and H3c—that is, for college students, PR and PC do not directly affect their  
5  
6 judgment of PV. Interestingly, the test of indirect effect shows that PR and PC influence  
7  
8 PV through the mediation effect of PB, and the path coefficient between PB and PV is  
9  
10 relatively large; therefore, PB is the key factor for college students to judge the value  
11  
12 of energy saving.  
13  
14  
15

16  
17 How is the contradiction between the results of this paper and the existing  
18  
19 literature explained? First, the structural model reflects the structural relationship  
20  
21 among latent variables, that is, when analyzing the relationship among PC, PR, PB and  
22  
23 PV, it is necessary to consider the influence of KRE. KRE has a significant direct  
24  
25 impact on both PR and PB, but college students will not directly judge the value of  
26  
27 energy saving based on them. Instead, they will take PR and PC as the basis to  
28  
29 comprehensively evaluate PB, and then evaluate PV according to PB. That is, although  
30  
31 KRE can simultaneously affect college students' judgment of PR and PB, it also causes  
32  
33 them to consider the core issue of whether energy saving is valuable. This point is  
34  
35 consistent with our thinking when we made relevant hypotheses, but it turns out that  
36  
37 KRE leads college students to believe that energy saving is valuable rather than  
38  
39 unnecessary. Based on the above results, we believe that under the influence of KRE,  
40  
41 college students will first evaluate PB (PR and PC will be considered simultaneously  
42  
43 in this process), and then evaluate PV based on PB. Therefore, how to improve college  
44  
45 students' PB of energy saving is the key to improving their energy-saving intentions,  
46  
47 and KRE plays an important role in this process.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 The indirect effect of KRE on PV is 0.248, which is larger than the path coefficient  
5  
6 of KRE to PR and KRE to PB, indicating that KRE significantly improves college  
7  
8 students' PV, and the degree of improvement is not low. Our original hypothesis stated  
9  
10 that the main function of KRE is to make college students realize that the energy  
11  
12 problem can be solved, and we assumed it would have a negative impact on PV and  
13  
14 INT. However, learning relevant knowledge can in fact enhance college students'  
15  
16 awareness of the value of energy saving. Combined with the discussion in 4.1, we  
17  
18 propose that learning KRE makes college students realize that energy saving will elicit  
19  
20 various benefits, so it forms a benefit-oriented value judgment. This is also similar to  
21  
22 the results of other studies; for example, knowledge of the potential benefits of energy-  
23  
24 saving products will enhance the intention to use such energy-saving products [9].  
25  
26  
27  
28  
29  
30  
31

### 32 **5.3 What affects the intention**

33  
34  
35 First, the path coefficient of PV to INT is large, and the indirect effect of PV on  
36  
37 INT is small, which indicates that INT is mainly directly affected by PV. That is, for  
38  
39 college students, “energy saving is valuable” is more essential than “energy saving is  
40  
41 necessary.” Relevant studies confirm this result. Zhao et al. has shown that the impact  
42  
43 of personal norms on energy-saving intentions is less than the perception of energy-  
44  
45 saving value [38]. Although some studies show that the impact of personal norms is  
46  
47 greater than knowledge or attitude, they set the connotation of knowledge or attitude as  
48  
49 relevant background knowledge [54] or perception of the cost of energy saving [55].  
50  
51 Combined with the studies, we determine that PV or PB has an obvious impact on the  
52  
53 energy-saving intentions of college students, and the impact is stronger than that of PN,  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 while PC have little influence. Therefore, the key is to enhance college students' PV of  
5  
6 energy saving through the teaching of systematic knowledge. It is not good practice to  
7  
8 simply and solely popularize background knowledge of the environment and energy or  
9  
10 to emphasize the necessity of energy saving.  
11  
12

13  
14 As a kind of energy-saving background knowledge, the total effect of KRE on INT  
15  
16 is 0.219, which is far lower than that of PV (0.744). Although this result shows that the  
17  
18 impact of KRE on INT is less than PV, as one of the means to enhance the PV (the total  
19  
20 effect of KRE on PV is 0.248), it is meaningful to spread this type of knowledge.  
21  
22 Moreover, the total effect of KRE on PN is 0.348, which indicates that KRE convinces  
23  
24 college students that energy saving is necessary. Through the accumulation of  
25  
26 background knowledge, via education, of energy, the environment and the progress of  
27  
28 technology, KRE can lead college students toward a more positive understanding of the  
29  
30 value of energy saving, and this understanding can work with KRE to enhance college  
31  
32 students' PN for energy saving; ultimately, this can enhance their energy-saving  
33  
34 intentions. This result also proves that if a college wants its students to develop self-  
35  
36 awareness of energy saving, one effective way to do so is to carry out systematic  
37  
38 education of energy knowledge.  
39  
40  
41  
42  
43  
44  
45  
46  
47

## 48 **6 Conclusion and policy implications**

49

50 Improving college students' energy-saving intentions is the key to reducing energy  
51  
52 consumption, improving the quality of national energy saving in the future and  
53  
54 achieving carbon neutral and sustainable development. Different types of knowledge to  
55  
56 which college students are exposed may pose different effects on their energy-saving  
57  
58  
59  
60

1  
2  
3  
4 intentions. Knowledge of renewable energy is one type of knowledge. In this paper, by  
5  
6 constructing hypotheses about the impact of the knowledge of renewable energy on  
7  
8 energy-saving intentions, a structural equation model is applied to verify the relevant  
9  
10 functioning paths. Through the research, the following conclusions were obtained: (1)  
11  
12 Knowledge of renewable energy has a positive impact on college students' energy-  
13  
14 saving intentions; (2) The impact is mainly realized through college students' perceived  
15  
16 value (PV) of energy saving. (3) Knowledge of renewable energy mobilizes college  
17  
18 students to evaluate the benefits of energy conservation, which is the key to enhancing  
19  
20 their energy-saving intentions; and (4) The impact of the knowledge of renewable  
21  
22 energy on personal norms is stronger than that on perceived value.  
23  
24  
25  
26  
27  
28  
29

30 Based on the conclusions, three implications can be put forward to help colleges  
31  
32 and society enhance the energy-saving intentions of college students through education  
33  
34 and knowledge popularization. First, strengthen the education and popularization of the  
35  
36 knowledge of renewable energy, which has a positive impact on college students'  
37  
38 energy-saving intentions. Through the curriculum, classroom education, offline  
39  
40 activities and information push of social platforms, college students' energy-saving  
41  
42 intentions can be effectively improved. Second, pay attention to the systematic  
43  
44 education of knowledge of renewable energy. The knowledge of renewable energy is a  
45  
46 type of technological progress knowledge; therefore, simply publicizing that renewable  
47  
48 energy can solve the energy problem may not be conducive to the energy-saving  
49  
50 intentions. In the process of education and popularization of the knowledge of  
51  
52 renewable energy, the energy background, technology development background and  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 processes, as well as the deficiencies of current technology should also be paid attention  
5  
6 to. Third, the process of education should focus on stimulating thinking about the  
7  
8 benefits and values of energy saving. Renewable energy, as a means and a technology  
9  
10 to solve energy problems, brings with it a risk of reducing the subjective intention of  
11  
12 energy saving of college students. However, if the relevant knowledge causes students  
13  
14 to consider and evaluate their own benefits from energy saving, their energy-saving  
15  
16 intentions will be improved. That said, some thoughts and discussions can be arranged  
17  
18 for college students in the process of knowledge education and popularization to  
19  
20 stimulate their thinking about the background of renewable energy technology and the  
21  
22 significance of energy saving.

25  
26  
27  
28

29  
30 This paper uses a structural equation model to investigate the impact of the  
31  
32 knowledge of renewable energy on college students' energy-saving intentions. Research  
33  
34 perspectives and data collection have revealed two limitations.. First, this paper mainly  
35  
36 studies knowledge of renewable energy from the perspective of college students,  
37  
38 therefore we must focus on the education and popularization of knowledge of  
39  
40 renewable energy from the perspective of college students. For this reason, we asked  
41  
42 the respondents about the intensity of their exposure to relevant knowledge from  
43  
44 different channels. It is worth noting that there may exist differences between the degree  
45  
46 of contact with knowledge and the degree of understanding of knowledge. In further  
47  
48 research, we will study the differences between the two aspects and their impact on  
49  
50 energy-saving intentions. Second, there are many types of knowledge that affect college  
51  
52 students' energy-saving intentions. This study focuses on the knowledge of renewable  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 energy and its impact on energy-saving intentions, so it does not involve other types of  
5  
6 knowledge. In future research, we will continue to explore other types of knowledge  
7  
8 that affect college students' energy-saving intentions and provide more comprehensive  
9  
10 and effective suggestions for promoting college students' energy-saving education.
